The objectives

An econometric study of dependence levels across several carbon markets around the world

The objectives

An econometric study of dependence levels accross several carbon markets around the world

"The ultimate objective of a global, worldwide carbon emission trading scheme".

An econometric study of dependence levels accross several carbon markets around the world

"The ultimate objective of a global, worldwide carbon emission trading scheme".

Q1: what are the hurdles ? Why are there so many markets ?

A copula-GARCH type model:

- (i) filtering of residuals, by an EGARCH model;

A copula-GARCH type model:

- (i) filtering of residuals, by an EGARCH model;
- (ii) parametric copulas for the joint law of the residuals.

A copula-GARCH type model:

- (i) filtering of residuals, by an EGARCH model;
- (ii) parametric copulas for the joint law of the residuals.

Q2: AR-EGARCH model for carbon prices or returns ? Returns, apparently... but are the series of prices and/or returns stationary ?

A copula-GARCH type model:

- (i) filtering of residuals, by an EGARCH model;
- (ii) parametric copulas for the joint law of the residuals.

Q2: AR-EGARCH model for carbon prices or returns ? Returns, apparently... but are the series of prices and/or returns stationary ?

Descriptive statistics of return distributions: apparently very different laws accross markets (Table 1 & 2).

Q3: is it still the case on an identical period of time ?

The goal is to evaluate copula parameters/tail-dependence parameters, with a parametric copula family.

Inference procedure

The goal is to evaluate copula parameters/tail-dependence parameters, with a parametric copula family.

The latter one is estimated by Canonical Maximum Likelihood, a semi-parametric method: no need for specifying a parametric law for the residuals.

The goal is to evaluate copula parameters/tail-dependence parameters, with a parametric copula family.

The latter one is estimated by Canonical Maximum Likelihood, a semi-parametric method: no need for specifying a parametric law for the residuals.

Nonetheless, it is assumed ε_t follows a Generalized Error Distribution

$$f(\varepsilon) \propto \exp\left(-|\varepsilon - \mu|^{\delta}/\gamma\right).$$

The latter one is estimated by Canonical Maximum Likelihood, a semi-parametric method: no need for specifying a parametric law for the residuals.

Nonetheless, it is assumed ε_t follows a Generalized Error Distribution

$$f(\varepsilon) \propto \exp\left(-|\varepsilon - \mu|^\delta/\gamma\right).$$

Q4: What can the specification GED be used for ?

The goal is to evaluate copula parameters/tail-dependence parameters, with a parametric copula family.

The latter one is estimated by Canonical Maximum Likelihood, a semi-parametric method: no need for specifying a parametric law for the residuals.

Nonetheless, it is assumed ε_t follows a Generalized Error Distribution

$$f(\varepsilon) \propto \exp\left(-|\varepsilon - \mu|^{\delta}/\gamma\right).$$

Q4: What can the specification GED be used for ?

Probably to apply Quasi-MLE of AR-EGARCH models... but it is pretty unusual...

Some parameters of the GED have to be fixed, so that $\mathbb{E}[\varepsilon_t] = 0$ (i.e. $\mu = 0$) and $\mathbb{E}[\varepsilon_t^2] = 1$ (not σ_t^2 !). But it remains $\delta...$

Some parameters of the GED have to be fixed, so that $\mathbb{E}[\varepsilon_t] = 0$ (i.e. $\mu = 0$) and $\mathbb{E}[\varepsilon_t^2] = 1$ (not σ_t^2 !). But it remains δ ...

Q5: is a value of δ imposed ? Is δ estimated ?

Some parameters of the GED have to be fixed, so that $\mathbb{E}[\varepsilon_t] = 0$ (i.e. $\mu = 0$) and $\mathbb{E}[\varepsilon_t^2] = 1$ (not σ_t^2 !). But it remains δ ...

Q5: is a value of δ imposed ? Is δ estimated ?

- ① Q6a: does the empirical distribution of the estimated residuals look like a GED ?

Some parameters of the GED have to be fixed, so that $\mathbb{E}[\varepsilon_t] = 0$ (i.e. $\mu = 0$) and $\mathbb{E}[\varepsilon_t^2] = 1$ (not σ_t^2 !). But it remains δ ...

Q5: is a value of δ imposed ? Is δ estimated ?

- 1 Q6a: does the empirical distribution of the estimated residuals look like a GED ?
- 2 Q6b: what if the underlying copula is parametrically estimated with GED marginal laws ?

Very small levels of dependence between carbon markets: Kendall's tau/Spearman's rho around a few percents, sometimes negative.

Very small levels of dependence between carbon markets: Kendall's tau/Spearman's rho around a few percents, sometimes negative.

The estimated copulas are not far from independence.

Tail dependence measures are close to zero.

Very small levels of dependence between carbon markets: Kendall's tau/Spearman's rho around a few percents, sometimes negative.

The estimated copulas are not far from independence.

Tail dependence measures are close to zero.

Q7: Any explanation ? The influence of time zones does not explain the whole phenomenon... is the integration of all these markets realistic/desired ?
